Ruby on Rails Application Deployment

29 November 2024 19:1

- 1. To successfully complete this DevOps project, follow these steps:
- 2. Step 1: Docker
 - Choose a Ruby on Rails Application: You can either use one of the provided example applications or create your own simple Rails app. The key is to ensure it uses a PostgreSQL database.
 - 2. Create a Dockerfile: Write a Dockerfile for your Rails application. This file will specify the base image (Ruby), install dependencies, set up the application code, and configure the application to run within a Docker container.
 - 3. Create a Dockerfile for PostgreSQL: Write a separate Dockerfile for the PostgreSQL database. This file will specify the PostgreSQL base image, set up any necessary configurations, and ensure the database is ready to accept connections.
 - 4. Build and Test: Build the Docker images for both the application and the database. Run the containers and test that the application can connect to the database and function correctly.
- 3. Step 2: Kubernetes
- **4. Push Images to Docker Hub (or your registry):** If you haven't already, push your my-rails-app and my-postgres-db images to Docker Hub or your preferred container registry. This will make them accessible to your Kubernetes cluster.
- 5. Create Kubernetes Manifests:
 - 1. Deployment (my-rails-app.yaml): Create a deployment for your Rails app. Make sure to update the image field with the full path to your Rails image on Docker Hub (e.g., <your dockerhub username>/my-rails-app).
 - **2. Service (my-rails-app-service.yaml):** Create a service to expose your Rails app. You can use a LoadBalancer type if you want to access it externally.
 - **3. StatefulSet (my-postgres-db.yaml):** Create a StatefulSet for your PostgreSQL database. Update the image field with the full path to your PostgreSQL image.
 - **4. Ingress (ingress.yaml):** If you want to use an Ingress controller, create an Ingress resource to route traffic to your Rails app service.
- 6. Set up a Kubernetes Cluster: Use Minikube, K3d, or any other local Kubernetes cluster.
- 7. Install Ingress Controller (optional): If you're using an Ingress, install the Ingress controller (e.g., Nginx Ingress) in your cluster.
- 8. Apply the Manifests: Use kubectl apply -f to apply your Kubernetes manifests to the cluster.
- **9. Verify Deployment:** Use kubectl get pods, kubectl get services, and other kubectl commands to verify that your application is running correctly in the cluster.

10.

- 1. Choose a Local Cluster: Install a local Kubernetes cluster provider like Minikube or K3d.
- 2. Write YAML Files: Create Kubernetes YAML files for your application and database.
 - a. Application: Define a Deployment to manage the Rails application pods.
 - **b. Database:** Use a StatefulSet to manage the PostgreSQL database pod. This ensures data persistence and stable network identities for the database.
- 3. **Ingress (Optional):** If you want to expose your application externally, set up an Ingress controller (like NGINX Ingress Controller) and create an Ingress resource to route traffic to your application.
- **4. Service Mesh (Optional):** If you need advanced traffic management and observability, consider using a service mesh like Istio or Linkerd.
- **5. Deploy and Test:** Apply the YAML files to your Kubernetes cluster. Test that the application is running correctly and accessible.
- 11. Step 3: ArgoCD
- **12. Create a Private GitHub Repository:** Create a private repository on GitHub and commit your Kubernetes manifests to it.
- **13. Install ArgoCD:** Follow the ArgoCD documentation to install it in your cluster.

14. Configure ArgoCD:

- 1. argocd-cm.yaml: Create a ConfigMap for ArgoCD with the necessary settings.
- 2. argocd-rbac-cm.yaml: Create a ConfigMap for ArgoCD RBAC configuration.
- **3. GitHub Secret:** Create a Kubernetes secret with your GitHub username and a personal access token (PAT) to allow ArgoCD to access your private repo.
- **4. application.yaml:** Create an ArgoCD Application resource to define your application and link it to your GitHub repository.
- **15. Deploy ArgoCD Configuration:** Apply the ArgoCD configuration files to your cluster.
- **16. Access ArgoCD UI:** Use kubectl port-forward to access the ArgoCD UI and monitor your application deployment.

17.

- 1. Create a Private GitHub Repository: Set up a private repository to store your Kubernetes manifests, Dockerfile, GitOps configurations, and pipeline configuration files.
- 2. Install ArgoCD: Deploy ArgoCD to your Kubernetes cluster.
- 3. Configure ArgoCD:
 - a. Create an `application.yaml` file to define the application you want ArgoCD to manage.
 - b. Set up ArgoCD ConfigMaps (`argocd-cm` and `argocd-rbac-cm`) for customization and role-based access control.
 - c. Configure ArgoCD to connect to your private GitHub repository.
- **4. GitOps Workflow:** Push your Kubernetes manifests to the GitHub repository. ArgoCD will automatically detect the changes and deploy them to your cluster.
- 18. Step 4: Tekton
- 19. Install Tekton: Install Tekton Pipelines and the Tekton Dashboard in your cluster.
- 20. Create Tekton Resources:
 - 1. **pipeline.yaml:** Define your Tekton pipeline to fetch the source code, build the image, push it to Docker Hub, and update your Kubernetes deployment.
 - **2.** task-kubectl-apply.yaml: Create a Tekton task to update your Kubernetes deployment with the new image.
 - **3.** Other Tasks (if needed): Define any other necessary tasks (e.g., git-clone, kaniko) if they are not available in your Tekton installation.
- **21. Run the Pipeline:** Use the Tekton Dashboard to create a PipelineRun, provide the required parameters, and start the pipeline.
- 22. Remember to:

23.

- 1. Install Tekton: Set up Tekton Pipelines and the Tekton Dashboard in your Kubernetes
- 2. Create a Pipeline: Define a Tekton Pipeline that performs the following tasks:
 - a. Download the source code from the public fork of your sample project.
 - b. Build a Docker image using the Dockerfile.
 - c. Push the image to Docker Hub.
- **3. Test the Pipeline:** Manually trigger the pipeline from the Tekton Dashboard and verify that it successfully builds and pushes the image.

24. Submission

- 1. Prepare the ZIP File: Create a ZIP file containing all the required configuration files (Kubernetes manifests, Dockerfile, GitOps configurations, pipeline configurations). Remember to exclude any sensitive information like SSH keys or deployment keys.
- **2. Record a Video Demo:** Create a video demonstrating the functionality of your application, the deployment process using ArgoCD, and the execution of the Tekton pipeline.
- **3. Submit:** Submit the ZIP file, video demo, and any additional relevant information through the provided submission link.

25. Remember:

- 1. **Thorough Testing:** Test each step of the process thoroughly to ensure everything works as expected.
- **2. Documentation:** Document your steps and decisions clearly. This will help you during the demo and troubleshooting.
- **3.** Clarity: Make sure your video demo is clear and concise, highlighting the key aspects of your implementation.
- **4.** Reach Out: If you have any questions, don't hesitate to contact the provided email address for clarification.

- 26. https://docs.google.com/document/d/15S3BIdAd057s88D310X2UjNnVGozZicrGNHB7UV3uPo/edit?tab=t.0
- **27.** To Convert whole repository into the one code.

```
28. const fs = require('fs');
29. const path = require('path');
30. const readline = require('readline');
31. const rl = readline.createInterface({
32. input: process.stdin,
33.
     output: process.stdout
34. });
35. const AUTO_INCLUDE = process.argv.includes('--auto-include');
36. async function promptUser(question) {
37.
    if (AUTO_INCLUDE) {
38.
        console.log(`${question} y`);
39.
        return 'y';
40.
      }
41.
     return new Promise((resolve) => {
42.
        rl.question(question, (answer) => {
43.
          resolve(answer);
44.
        });
45.
      });
46. }
47. async function selectFiles(currentDir, excludePatterns) {

  105.
  106.
         rl.close();
  107. }
  108. main().catch((error) => {
  109.
           console.error('An error occurred:', error);
  110.
         rl.close();
  111. });
* 112. Commands to install ruby on Linux
\rightarrow 113. sudo apt update
→ 114. sudo apt install build-essential zlib1g-dev libssl-dev libreadline-dev libyaml-dev libsglite3-dev sglite3
        libxml2-dev libxslt1-dev autoconf libgmp-dev
\rightarrow 115.
          git clone <a href="https://github.com/rbenv/rbenv.git">https://github.com/rbenv/rbenv.git</a> ~/.rbenv
\rightarrow 116.
           echo 'export PATH="$HOME/.rbenv/bin:$PATH"" >> ~/.bashrc

ightarrow 117.
           echo 'eval "$(rbenv init -)"' >> ~/.bashrc

ightarrow 118.
          source ~/.bashrc

ightarrow 119.
          git clone <a href="https://github.com/rbenv/ruby-build.git">https://github.com/rbenv/ruby-build.git</a> ~/.rbenv/plugins/ruby-build
\rightarrow 120. rbenv install -l
\rightarrow 121. rbenv global 3.2.2

ightarrow 122.
          ruby -v
\rightarrow 123.
          gem install rails
\rightarrow 124.
   125. Now uploading application on ubuntu.
\rightarrow 126. git push -f origin main
   127. Now inside on ubuntu linux application repository we will create and docker image of the
         application.
\rightarrow 128. vim Dockerfile
\rightarrow 129. FROM ruby:3.1
\rightarrow 130. WORKDIR /app
```

```
\rightarrow 132. RUN bundle install
\rightarrow 133. COPY...
→ 134. RUN bundle exec rails db:create
→ 135. RUN bundle exec rails db:migrate
\rightarrow 136. EXPOSE 3000
→ 137. CMD ["rails", "server", "-b", "0.0.0.0"]
→ 138. vim Dockerfile.postgres
\rightarrow 139. FROM postgres:14

ightarrow 140. ENV POSTGRES USER=

ightarrow 141. ENV POSTGRES_PASSWORD=
\rightarrow 142. ENV POSTGRES_DB=
\rightarrow 143. docker build -t my-rails-app.
→ 144. docker-compose.yml
\rightarrow 145. version: "3.9"
\rightarrow 146. services:
\rightarrow 147. web:
\rightarrow 148. build: .
\rightarrow 149. ports:
→ 150. - "3000:3000"
\rightarrow 151. depends_on:
\rightarrow 152. - db
\rightarrow 153. environment:

ightarrow 154. - DATABASE_HOST=db

ightarrow 155. - DATABASE_USER=
\rightarrow 156. - DATABASE_PASSWORD=
            - DATABASE_NAME=

ightarrow 157.
\rightarrow 158. db:
\rightarrow 159. image: postgres:14
\rightarrow 160. environment:

ightarrow 161. - POSTGRES_USER= 
ightarrow 162. - POSTGRES_PASSWORD=
\rightarrow 163. - POSTGRES DB=
```

→ 131. COPY Gemfile Gemfile.lock ./

164. Explanation:

- 1. depends_on: This ensures that the db container starts before the web container.
- 2. environment: These variables provide the database connection details to your Rails app. The DATABASE_HOST is set to db, which is the service name of your PostgreSQL container within the Docker Compose network. This allows the Rails app to connect to the database container.
- **165. Clean Up and Retry:** Sometimes, cleaning up old containers, images, and networks can help resolve issues. Try these commands:
- \rightarrow 166. docker-compose down --rmi all --volumes
- \rightarrow 167. docker system prune -a

- 168. So the big challenge came needs to run the postgre container mainually from the image and then assign its ip address to the conif database.yml file in db section so that rails image can be build and run the container while connecting to the postgre database using ip.
- → 169. docker run -d --name my-postgres-db -e POSTGRES_USER=? -e POSTGRES_PASSWORD=-e POSTGRES DB= my-postgres-db
- \rightarrow 170. af24e2ee2956b5b7e650311b9133c2cd853d474816aca3dcd35a043e1c1e6725
- → 171. docker run -d --name my-rails-app -p 3000:3000 -e DATABASE_HOST=my-postgres-db -e DATABASE_USER=? -e DATABASE_PASSWORD= -e DATABASE_NAME= my-rails-app

→ 341. kubectl apply -f argocd-rbac-cm.yaml
→ 342. kubectl apply -f github-repo-secret.yaml
→ 343. kubectl apply -f application.yaml
```

344. Access ArgoCD UI: Use kubectl port-forward service/argocd-server 8080:443 to access the ArgoCD UI and monitor your application deployment.

ightarrow 345. kubectl port-forward service/argocd-server -n argocd 8080:443 346. To get the password. ightarrow 347. kubectl -n argocd get secret argocd-initial-admin-secret -o jsonpath="{.data.password}" | base64 -d 348. RUN BOTH CONATINERS MINIKUBECLUSTER 349. kubectl port-forward service/argocd-server -n argocd 8080:443 \rightarrow 350. kubectl get pods -n argocd → 351. kubectl delete namespace argocd → 352. kubectl create namespace argocd → 353. kubectl apply -n argocd -f https://raw.githubusercontent.com/argoproj/argocd/stable/manifests/install.yaml → 354. kubectl port-forward service/argocd-server -n argocd 8080:443 355. Now we will install tekton pipeline and the tekton dashboard in the cluster. → 356. kubectl apply --filename https://storage.googleapis.com/tekton- releases/pipeline/latest/release.yaml 357. Tetkon Triggers \rightarrow 358. kubectl apply --filename \ → 359. https://storage.googleapis.com/tekton-releases/triggers/latest/release.yaml \rightarrow 360. kubectl apply --filename \ → 361. https://storage.googleapis.com/tekton-releases/triggers/latest/interceptors.yaml 362. Tetkon Dashboard ightarrow 363. kubectl apply --filename https://storage.googleapis.com/tektonreleases/dashboard/latest/release.yaml 364. Install the Task 365. kubectl apply -f https://api.hub.tekton.dev/v1/resource/tekton/task/kaniko/0.6/raw 366. Create a pipeline.yaml: → 367. apiVersion: tekton.dev/v1beta1 \rightarrow 368. kind: Pipeline \rightarrow 369. metadata: ightarrow 370. name: my-rails-app-pipeline \rightarrow 371. spec: \rightarrow 372. workspaces: ightarrow 373. - name: shared-workspace \rightarrow 374. params: \rightarrow 375. - name: image-name \rightarrow 376. type: string → 377. default: <your_dockerhub_username>/my-rails-app \rightarrow 378. tasks: \rightarrow 379. - name: fetch-repository

```
ightarrow 380.
           taskRef:
 → 381.
            name: git-clone
\rightarrow 382. workspaces:
\rightarrow 383. - name: output
            workspace: shared-workspace

ightarrow 384.
\rightarrow 385. params:
\rightarrow 386. - name: url

ightarrow 387.
            value: <your_public_github_repo_url>

ightarrow 388.
            - name: revision

ightarrow 389.
            value: main # Or your branch name
→ 390. - name: build-and-push-image
\rightarrow 391. taskRef:

ightarrow 392.
            name: kaniko
\rightarrow 393. runAfter:
\rightarrow 394. - fetch-repository
\rightarrow 395. workspaces:
\rightarrow 396. - name: source

ightarrow 397.
            workspace: shared-workspace
\rightarrow 398. params:

ightarrow 399.
           - name: IMAGE
\rightarrow 400. value: $(params.image-name)
\rightarrow 401. - name: DOCKERFILE

ightarrow 402.
            value: Dockerfile
→ 403. - name: update-k8s-deployment
\rightarrow 404. taskRef:
\rightarrow 405. name: kubectl-apply
\rightarrow 406. runAfter:
\rightarrow 407. - build-and-push-image
\rightarrow 408. params:

ightarrow 409.
           - name: PATH_TO_YAML_FILE
\rightarrow 410. value: my-rails-app.yaml
→ 411. - name: Yaml_parameters

ightarrow 412.
             value: "image=$(params.image-name)"
   413. Create a task-kubectl-apply.yaml: This task updates your Kubernetes deployment with the new
          image.
→ 414. apiVersion: tekton.dev/v1beta1
\rightarrow 415. kind: Task
\rightarrow 416. metadata:
\rightarrow 417. name: kubectl-apply
\rightarrow 418. spec:
\rightarrow 419. params:

ightarrow 420. - name: PATH TO YAML FILE
\rightarrow 421. type: string
\rightarrow 422. description: Path to the YAML file to apply
\rightarrow 423. - name: Yaml_parameters
\rightarrow 424. type: string
            description: 'Set parameters for the Yaml file'

ightarrow 425.
\rightarrow 426. steps:
\rightarrow 427. - name: apply-manifests
→ 428. image: lachlanevenson/k8s-kubectl:latest # Or another kubectl image

ightarrow 429.
           command:

ightarrow 430.
            - /bin/bash

ightarrow 431.
            args:

ightarrow 432.
            - -C

ightarrow 433.
            - [
```

- → 434. sed -i "s@<your_dockerhub_username>/my-rails-app@\$Yaml_parameters@g" \$PATH_TO_YAML_FILE
- → 435. kubectl apply -f \$PATH_TO_YAML_FILE
- → 436. sudo lsof -i -P | grep LISTEN
- \rightarrow 437. kubectl get services --all-namespaces
 - 438. To run Tetkon Dashboard on port 8081 local.
- ightarrow 439. $\,$ kubectl port-forward service/tekton-dashboard -n tekton-pipelines 8081:9097 $\,$
- → 440. kubectl describe service -n tekton-pipelines tekton-dashboard
- → 441. kubectl logs -n tekton-pipelines <tekton-dashboard-pod-name>
- → 442. kubectl get pods -n tekton-pipelines
- ightarrow 443. kubectl rollout restart deployment -n tekton-pipelines tekton-dashboard

444. 2. Configure Git Credentials

- 1. Create a Kubernetes secret: You need a secret to store your Git credentials (username and personal access token or password). This will allow your Tekton pipeline to authenticate with your Git repository.
- 445. apiVersion: v1
- 446. kind: Secret
- 447. metadata:
- 448. name: git-credentials
- 449. type: kubernetes.io/basic-auth
- 450. data:
- 451. username: <base64-encoded-username>
- 452. password: <base64-encoded-pat-or-password>
- 453. Replace <base>64-encoded-username> with the base
64-encoded value of your Git username.
- 454. Replace <base>64-encoded-pat-or-password> with the base
64-encoded value of your Git personal access token (PAT) or password.
- 455. 1. Replace Placeholders
- 456. Open your pipeline.yaml file in a text editor.
- 457. Locate the following placeholders and replace them with your actual values:
 - 1. <your_public_github_repo_url>: The URL of your public GitHub repository where your Rails app code is located.
 - 2. <image_with_git_and_sed>: A Docker image that has git and sed installed (e.g., ubuntu:latest, alpine/git).
 - 3. <old_image_tag>: The current image tag in your my-rails-app.yaml deployment manifest that you want to replace.
 - 4. <new_image_tag>: The new image tag you want to use (e.g., my-rails-app:v2, my-rails-app:latest).
 - 5. <image_with_argocd_cli>: A Docker image that has the Argo CD CLI installed (e.g., argoproj/argocd).

458. Define the Tasks

459. You'll need to create separate YAML files to define the update-manifest-task and sync-argocd-task

Tasks. These tasks will contain the steps that you previously had directly in the Pipeline.

460. Here's an example of how you can define the update-manifest-task:

```
→ 461. apiVersion: tekton.dev/v1beta1
\rightarrow 462. kind: Task
\rightarrow 463. metadata:
→ 464. name: update-manifest-task
\rightarrow 465. spec:
\rightarrow 466. workspaces:
\rightarrow 467. - name: source
\rightarrow 468. steps:
\rightarrow 469. - name: update-image-tag
\rightarrow 470. image: ubuntu:latest
→ 471. workingDir: $(workspaces.source.path)
\rightarrow 472. command:
\rightarrow 473. - /bin/bash
\rightarrow 474. args:
→ 475. --c
\rightarrow 476. -

    → 477. sed -i 's/my-rails-app.yaml/my-rails-app:latest/g' my-rails-app.yaml
    → 478. git config user.email "tekton@example.com"
    → 479. git config user.name "Tekton"
    → 480. git add my-rails-app.yaml
    → 481. git commit -m "Update image tag"
    → 482. git config credential.helper 'store --file=/etc/git-credentials'
    → 483. git push origin main

\rightarrow 484. volumeMounts:
\rightarrow 485. - name: git-credentials

ightarrow 486.
                 mountPath: /etc/git-credentials
\rightarrow 487. volumes:
→ 488. - name: git-credentials
\rightarrow 489. secret:

ightarrow 490.
              secretName: git-credentials
```

491. Similarly, you can create a sync-argocd-task.yaml file to define the sync-argocd-task.

```
→ 492. apiVersion: tekton.dev/v1beta1
\rightarrow 493. kind: Task
\rightarrow 494. metadata:
\rightarrow 495. name: sync-argocd-task
\rightarrow 496. spec:
\rightarrow 497. steps:
\rightarrow 498. - name: argocd-sync
→ 499. image: argoproj/argocd
\rightarrow 500. command:

ightarrow 501. -/bin/bash
\rightarrow 502. args:
\rightarrow 503. --c
\rightarrow 504.
             - |
\rightarrow 505.
             argocd app sync my-rails-app
```

506. Explanation

- 1. apiVersion: This specifies the API version for the Tekton Task object.
- 2. kind: This indicates that the YAML defines a Tekton Task.

- 3. metadata.name: This sets the name of the task to sync-argocd-task. You'll use this name to refer to the task in your pipeline.yaml.
- 4. spec.steps: This section defines the steps that will be executed within the task.
 - a. name: The name of the step (argocd-sync).
 - b. image: The Docker image to use for this step (argoproj/argocd, which contains the Argo CD CLI).
 - c. command: The command to execute within the container (/bin/bash).
 - d. args: The arguments to pass to the command. In this case, it's a script that runs argord app sync my-rails-app to synchronize your Argo CD application.

507. Apply the tasks

508. Apply these task definitions to your cluster:

- ightarrow 509. kubectl apply -f update-manifest-task.yaml -n tekton-pipelines
- → 510. kubectl apply -f sync-argocd-task.yaml -n tekton-pipelines
- ightarrow 511. kubectl describe service -n tekton-pipelines tekton-pipelines-webhook
- → 512. kubectl logs -n tekton-pipelines <webhook-pod-name>
- → 513. kubectl get pods -n tekton-pipelines -l app=tekton-pipelines-webhook
- ightarrow 514. kubectl get pods -n tekton-pipelines

kubectl get pods -n tekton-pipelines -l app=tekton-pipelines-webhook -o jsonpath='{.items[0].spec.containers[0].image}'

- → 515. kubectl apply -f update-manifest-task.yaml -n tekton-pipelines
- → 516. kubectl apply -f sync-argocd-task.yaml -n tekton-pipelines
 - 1. kubectl apply -f pipeline.yaml -n tekton-pipelines

517. Replace with your PVC name

- 1. claimName: pvc-for-workspace
 - a. This line is within the workspaces section of the pipelinerun.yaml file.
 - b. Replace "pvc-for-workspace" with the actual name of the Persistent Volume Claim (PVC) you created for your Tekton workspace.
 - c. If you haven't created a PVC yet, you'll need to create one. Here's a simple example of a PVC YAML file:
- \rightarrow 518. apiVersion: v1
- ightarrow 519. kind: PersistentVolumeClaim
- \rightarrow 520. metadata:
- \rightarrow **521.** name: my-workspace-pvc
- \rightarrow 522. namespace: tekton-pipelines
- \rightarrow 523. spec:
- \rightarrow 524. accessModes:
- \rightarrow 525. ReadWriteOnce
- \rightarrow 526. resources:
- \rightarrow 527. requests:
- \rightarrow 528. storage: 1Gi
 - 529. Create Pipelinerun.yaml -
 - 530. apiVersion: tekton.dev/v1beta1
 - 531. kind: PipelineRun
 - 532. metadata:

```
533. name: my-rails-app-run-1
  534. namespace: tekton-pipelines
  535. spec:
  536. pipelineRef:
  537. name: my-rails-app-pipeline
  538. params:
  539. - name: url
540. value: <a href="https://github.com/sansugupta/Budget-App.git">https://github.com/sansugupta/Budget-App.git</a>
  541. - name: revision
  542. value: main
  543. serviceAccountName: dockerhub-service-account
  544. workspaces:
  545. - name: shared-workspace
         persistentVolumeClaim:
claimName:
  546.
  547.
                 claimName: my-workspace-pvc
   548. Docker Service Account -
→ 549. kubectl get serviceaccounts --all-namespaces
→ 550. kubectl get serviceaccounts -n tekton-pipelines
→ 551. vim dockerhub-secret.yaml
   552. Here's how to create the service account and secret:
            1. Create the secret:
                  a. Create a YAML file named dockerhub-secret.yaml with the following content:
\rightarrow 553. apiVersion: v1
\rightarrow 554. kind: Secret
\rightarrow 555. metadata:
→ 556. name: dockerhub-secret
→ 557. namespace: tekton-pipelines
→ 558. type: kubernetes.io/dockerconfigjson
\rightarrow 559. data:
→ 560. .dockerconfigison: <base64-encoded-docker-config>
   561. Replace <a href="https://example.com/sep-44-encoded-docker-config">base64-encoded-docker-config</a> with the base64-encoded string of your Docker Hub
         credentials in the following format:
   562. Replace <a href="https://example.com/saspace/base64-encoded-username-and-password">base64-encoded-username-and-password</a> with the base64-encoded string of
         your_dockerhub_username:your_dockerhub_password.
   563. Create the service account:
            1. Create a YAML file named dockerhub-service-account.yaml with the following content:
\rightarrow 564. apiVersion: v1
```

```
    → 565. kind: ServiceAccount
    → 566. metadata:
    → 567. name: dockerhub-service-account
    → 568. namespace: tekton-pipelines
    → 569. secrets:
    → 570. - name: dockerhub-secret
    →
    →
    → 571. vim config.json
    572. {
```

```
"auths": {
  573.
               "https://index.docker.io/v1/": {
  574.
                 "auth": "c2Fuc3VndXB0YTpqaG9uY2VuYUA5NjY="
  575.
  576.
  577.
             }
          }
  578.
→ 579. sanskar@SANSKAR:~/Budget-App$ base64 config.json
→ 580. kubectl apply -f dockerhub-secret.yaml
→ 581. kubectl apply -f dockerhub-service-account.yaml
→ 582. kubectl get serviceaccounts -n tekton-pipelines
→ 583. kubectl get secrets -n tekton-pipelines
   584. Git-Clone for Tekton -
→ 585. kubectl apply -f https://api.hub.tekton.dev/v1/resource/tekton/task/git-clone/0.9/raw -n tekton-
        pipelines
→ 586. tekton-dashboard-role.yaml
  587. apiVersion: rbac.authorization.k8s.io/v1
  588. kind: Role
  589. metadata:
  590. name: tekton-dashboard-role
  591.
        namespace: tekton-pipelines
  592. rules:
  593. - apiGroups: [""]
  594. resources: ["configmaps"]
  595. verbs: ["get", "list", "watch"]
→ 596. tekton-dashboard-rolebinding.yaml
  597. apiVersion: rbac.authorization.k8s.io/v1
  598. kind: RoleBinding
  599. metadata:
  600. name: tekton-dashboard-rolebinding
  601. namespace: tekton-pipelines
  602. subjects:
  603. - kind: ServiceAccount
  604. name: tekton-dashboard
  605. roleRef:
  606. kind: Role
